

NEXT GENERATION FIREWALL TEST REPORT

Sophos XG Firewall 750 SFOS v17.0.7 MR7

SEPTEMBER 13, 2018

Authors – Devon James, Michael Shirley, Tim Otto

Overview

This document provides test results for the Sophos XG Firewall 750 SFOS v17 MR7.

During the NSS Labs 2018 Next Generation Firewall (NGFW) Group Test, the Sophos XG Firewall 750 SFOS v17 MR7 failed to detect 12 evasions. This affected its placement in NSS' 2018 NGFW Security Value Map (SVM)™.

After working closely with NSS, Sophos updated its software and released Sophos XG Firewall 750 SFOS v17.0.7 MR7. The updated device was subjected to testing under the same NGFW Test Methodology (v8.0) and appropriately handled 190 out of the 190 evasions it was tested against. Furthermore, the XG 750 improved its exploit block rate by 1.3% and improved its performance by 350 Mbps.

NSS research indicates that NGFW devices are typically deployed to protect users rather than data center assets, and that the majority of enterprises will not separately tune intrusion prevention system (IPS) modules within their NGFWs. Therefore, during NSS testing, NGFW products are configured with the vendor's pre-defined or recommended (i.e., "out-of-the-box") settings in order to provide readers with relevant security effectiveness and performance dimensions based on their expected usage.

Product	NSS-Tested Throughput		3-Year TCO (US\$)
	6,194 Mbps		\$32,112
Sophos XG Firewall 750 SFOS v17.0.7 MR7	Exploit Block Rate ¹	Evasions Blocked ²	Stability & Reliability
	94.8%	190/190	PASS

Figure 1 – Overall Test Results

Using the recommended policy, the XG Firewall 750 blocked 94.8 % of attacks. The device proved effective against 190 out of 190 evasions tested. The device passed all stability and reliability tests.

The XG Firewall 750 is rated by NSS at 6,194 Mbps, which is lower than the vendor-claimed performance; Sophos rates this device at 11,800 Mbps. *NSS-Tested Throughput* is calculated as a weighted average of the traffic that NSS expects an NGFW to experience in an enterprise environment. For more details, please see Appendix A: Product Scorecard.

This report is Confidential and is expressly limited to NSS Labs' licensed users.

¹ Exploit block rate is defined as the number of live exploits and exploits from the NSS Exploit Library blocked under test.

² In accordance with the industry standard for vulnerability disclosures and to provide vendors with sufficient time to add protection where necessary, NSS Labs will not publicly release information about which previously unpublished techniques were applied during testing until 90 days after the publication of this document.

Security Effectiveness

The firewall market is one of the largest and most mature security markets. Firewalls have undergone several stages of development, from early packet filtering and circuit relay firewalls to application-layer (proxy-based) and dynamic packet filtering firewalls. Throughout their history, however, the goal has been to enforce an access control policy between two networks, and they should therefore be viewed as an implementation of policy.

A firewall is a mechanism used to protect a trusted network from an untrusted network, while allowing authorized communications to pass from one side to the other, thus facilitating secure business use of the Internet. With the emergence of HTML 5, web browsers and security threats, however, firewalls are evolving further. NGFWs traditionally have been deployed to defend the network on the edge, but some enterprises have expanded their deployment to include internal segmentation.

As Web 3.0 trends push critical business applications through firewall ports that previously were reserved for a single function, such as HTTP, legacy firewall technology is effectively blinded. It is unable to differentiate between actual HTTP traffic and non-HTTP services tunneling over port 80, such as VoIP or instant messaging. Today, application-level monitoring must be performed in addition to analysis of port and destination. Firewalls are evolving to address this increased complexity.

It is no longer possible to rely on port and protocol combinations alone to define network applications. The NGFW must be capable of determining which applications are running regardless of which ports they are using and thus secure them effectively. This section verifies that the device is capable of enforcing the security policy effectively.

NSS Exploit Library

NSS' security effectiveness testing leverages the deep expertise of our engineers who utilize multiple commercial, open-source, and proprietary tools as appropriate. With more than 1,900 exploits, this is the industry's most comprehensive test to date.

Product	Total Number of	Total Number of	Block
	Attacks Run	Attacks Blocked	Percentage
Sophos XG Firewall 750 SFOS v17.0.7 MR7	2,074	1,996	96.24%

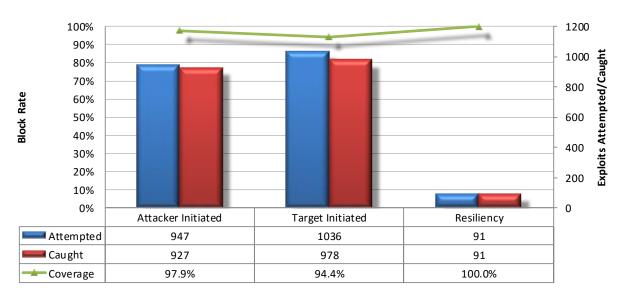

Figure 2 - Number of Attacks Blocked (%)

False Positive Testing

Any signature that blocks non-malicious traffic during false-positive testing is disabled for security testing.

Coverage by Attack Vector

Because a failure to block attacks could result in significant compromise and could severely impact critical business systems, NGFWs should be evaluated against a broad set of exploits. Exploits can be categorized as either attacker-initiated or target-initiated. Attacker-initiated exploits are threats executed remotely against a vulnerable application and/or operating system by an individual, while target-initiated exploits are initiated by the vulnerable target. Target-initiated exploits are the most common type of attack experienced by the end user, and the attacker has little or no control as to when the threat is executed. NSS also measured the resiliency of a device by

introducing previously unseen variations of a known exploit and measuring the device's effectiveness against them.

Figure 3 - Coverage by Attack Vector and Resiliency

Coverage by Impact Type

The most serious exploits are those that result in a remote system compromise, providing the attacker with the ability to execute arbitrary system-level commands. Most exploits in this class are "weaponized" and offer the attacker a fully interactive remote shell on the target client or server. Slightly less serious are attacks that result in individual service compromise but not arbitrary system-level command execution, but this distinction is becoming less relevant in the modern threat landscape. Finally, there are attacks that result in a system- or service-level fault that crashes the targeted service or application and requires administrative action to restart the service or reboot the system. Clients can contact NSS for more information about these tests.

Coverage by Date

Figure 4 provides insight into whether or not a vendor is aging out protection signatures aggressively enough to preserve performance levels. It also reveals whether a product lags behind in protection for the most current vulnerabilities. NSS reports exploits by individual years for the past ten years. Exploits older than ten years are grouped together.

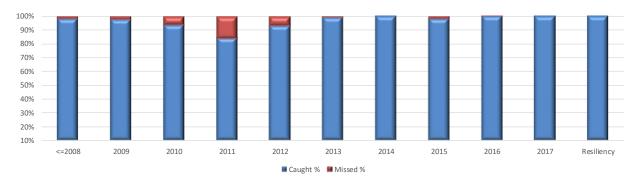

Figure 4 – Product Coverage by Date

Coverage by Target Vendor

Exploits within the *NSS Exploit Library* target a wide range of protocols and applications. Figure 5 depicts the coverage offered by the XG Firewall 750 for five of the top vendors targeted in this test. More than 70 vendors are represented in the test. Clients can contact NSS for more information about this test.

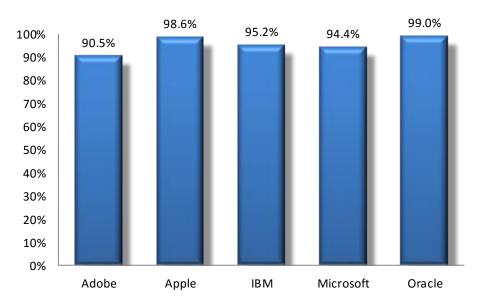

Figure 5 - Product Coverage by Target Vendor

Live Exploits

This test uses NSS' continuous live testing capabilities to determine how effective products are at blocking exploits that are being used, or that have been used in active attack campaigns.³

Protection from web-based exploits targeting client applications, also known as "drive-by" downloads, can be effectively measured in NSS' unique live test harness through a series of procedures that measure the stages of protection. Unlike traditional malware that is downloaded and installed, "drive-by" attacks first exploit a vulnerable application then silently download and install malware. For more information, see the Comparative Report on Security.

Product	Block Percentage
Sophos XG Firewall 750 SFOS v17.0.7 MR7	89.25%

Figure 6 - Number of Attacks Blocked (%)

-

³ See the NSS Continuous Security Validation Platform for more details.

Resistance to Evasion Techniques

Evasion techniques are a means of disguising and modifying attacks at the point of delivery to avoid detection and blocking by security products. Failure of a security device to correctly identify a specific type of evasion potentially allows an attacker to use an entire class of exploits for which the device is assumed to have protection. This often renders the device virtually useless. Many of the techniques used in this test have been widely known for years and should be considered minimum requirements for the NGFW product category.

Providing exploit protection results without fully factoring in evasions can be misleading. The more classes of evasion that are missed (such as HTTP evasions, IP packet fragmentation, TCP stream segmentation, RPC fragmentation, URL obfuscation, HTML obfuscation, resiliency, and FTP evasion), the less effective the device. For example, it is better to miss all techniques in one evasion category, such as FTP evasion, than one technique in each category, which would result in a broader attack surface.

Furthermore, evasions operating at the lower layers of the network stack (IP packet fragmentation or stream segmentation) have a greater impact on security effectiveness than those operating at the upper layers (HTTP or FTP obfuscation.) Lower-level evasions will potentially impact a wider number of exploits; missing TCP segmentation, for example, is a much more serious issue than missing FTP obfuscation.

TCP Split Handshake attacks can deceive the IPS engine into believing that the traffic flow is reversed and the IPS does not need to scan the content, which exposes the NGFW to previously known attacks.

The resiliency of a system can be defined as its ability to absorb an attack and reorganize around a threat. When an attacker is presented with a vulnerability, the attacker can select one or more paths to trigger the vulnerability. NSS will introduce various, previously unseen variations of exploits to exploit the vulnerability and measure the device's effectiveness against them. A resilient device will be able to detect and prevent against different variations of the exploit. For more details, see the Evasions Test Methodology v1.1 at www.nsslabs.com. Figure 7 provides the results of the evasion tests for the XG Firewall 750.

Test Procedure	Result
RPC Fragmentation	PASS
URL Obfuscation	PASS
FTP/Telnet Evasion	PASS
HTML Evasions	PASS
IP Packet Fragmentation + TCP Segmentation	PASS
HTTP Evasions	PASS
TCP Split Handshake	PASS
Resiliency ⁴	
Attacks on nonstandard ports ⁵	PASS

Figure 7 – Resistance to Evasion Results

⁴ The results of resiliency testing are included in the Exploit Block Rate calculations.

⁵ Enterprises should be aware of the importance of egress filtering and should ensure their configurations mitigate these risks.

Performance

There is frequently a trade-off between security effectiveness and performance. Because of this trade-off, it is important to judge a product's security effectiveness within the context of its performance and vice versa. This ensures that new security protections do not adversely impact performance and that security shortcuts are not taken to maintain or improve performance.

Raw Packet Processing Performance (UDP Throughput)

This test uses UDP packets of varying sizes generated by test equipment. A constant stream of the appropriate packet size along with variable source and destination IP addresses is transmitted bidirectionally through each port pair of the device.

Each packet contains dummy data and is targeted at a valid port on a valid IP address on the target subnet. The percentage load and frames per second (fps) figures across each inline port pair are verified by network monitoring tools before each test begins. Multiple tests are run and averages are taken where necessary.

This traffic does not attempt to simulate any "real-world" network condition. The aim of the test is to determine the raw packet processing capability of each inline port pair of the device as well as the device's effectiveness at forwarding packets quickly, in order to provide the highest level of network performance with the least amount of latency.

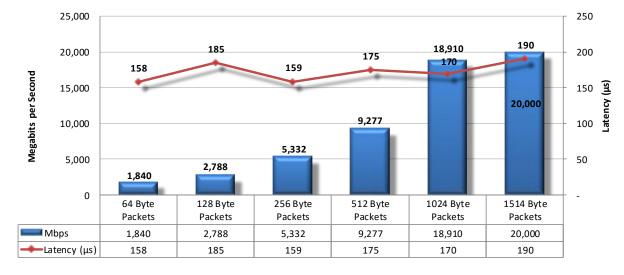

Figure 8 – Raw Packet Processing Performance (UDP Traffic)

Raw Packet Processing Performance (UDP Latency)

NGFWs that introduce high levels of latency lead to unacceptable response times for users, especially where multiple security devices are placed in the data path. Figure 9 depicts UDP latency (in microseconds) as recorded during the UDP throughput tests at 90% of maximum load.

Latency – UDP	Microseconds
64-Byte Packets	158
128-Byte Packets	185
256-Byte Packets	159
512-Byte Packets	175
1024-Byte Packets	170
1514-Byte Packets	190

Figure 9 - UDP Latency in Microseconds

Maximum Capacity

The use of traffic generation appliances allows NSS engineers to create "real-world" traffic at multi-Gigabit speeds as a background load for the tests. The aim of these tests is to stress the inspection engine and determine how it copes with high volumes of TCP connections per second, application-layer transactions per second, and concurrent open connections. All packets contain valid payload and address data, and these tests provide an excellent representation of a live network at various connection/transaction rates.

Note that in all tests the following critical "breaking points"—where the final measurements are taken—are used:

- Excessive concurrent TCP connections Latency within the NGFW is causing an unacceptable increase in open connections.
- Excessive concurrent HTTP connections Latency within the NGFW is causing excessive delays and increased response time.
- Unsuccessful HTTP transactions Normally, there should be zero unsuccessful transactions. Once these appear, it is an indication that excessive latency within the NGFW is causing connections to time out.

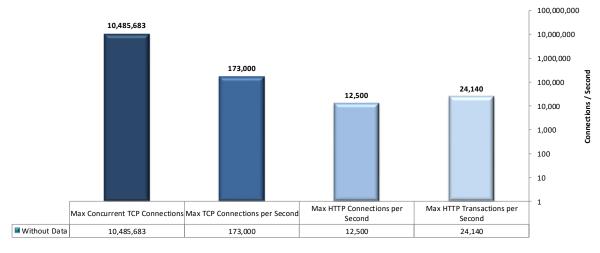

Figure 10 – Concurrency and Connection Rates

HTTP Capacity

The aim of the HTTP capacity tests is to stress the HTTP detection engine and determine how the device copes with network loads of varying average packet size and varying connections per second. By creating multiple tests using genuine session-based traffic with varying session lengths, the device is forced to track valid HTTP sessions, thus ensuring a higher workload than for simple packet-based background traffic.

Each transaction consists of a single HTTP GET request. All packets contain valid payload (a mix of binary and ASCII objects) and address data. This test provides an excellent representation of a live network (albeit one biased toward HTTP traffic) at various network loads.

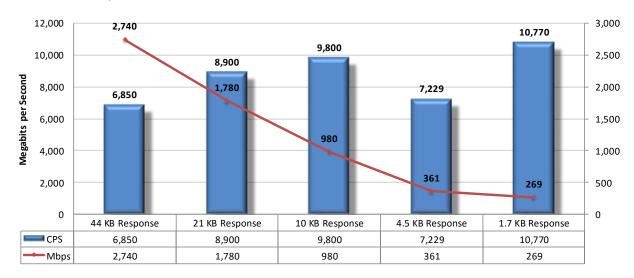

Figure 11 – HTTP Capacity

Application Average Response Time – HTTP

Application Average Response Time – HTTP (at 90% Maximum Load)	Milliseconds
2,500 Connections per Second – 44 KB Response	38.89
5,000 Connections per Second – 21 KB Response	37.54
10,000 Connections per Second – 10 KB Response	34.08
20,000 Connections per Second – 4.5 KB Response	31.56
40,000 Connections per Second – 1.7 KB Response	34.49

Figure 12 – Average Application Response Time (Milliseconds)

HTTP Capacity with HTTP Persistent Connections

This test will use HTTP persistent connections, with each TCP connection containing 10 HTTP GETs and associated responses. All packets contain valid payload (a mix of binary and ASCII objects) and address data, and this test provides an excellent representation of a live network at various network loads. The stated response size is the total of all HTTP responses within a single TCP session.

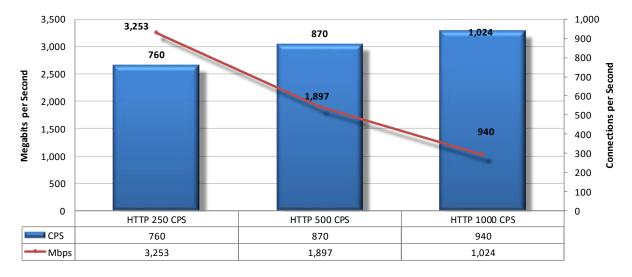

Figure 13 - HTTP Capacity HTTP Persistent Connections

Single Application Flows

This test measures the performance of the device with single application flows. For details about single application flow testing, see the NSS Labs Next Generation Firewall Test Methodology, available at www.nsslabs.com.

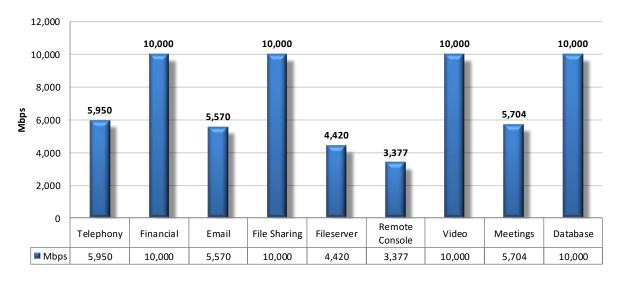

Figure 14 – Single Application Flows

SSL/TLS

Use of the Secure Sockets Layer (SSL) protocol and its newer iteration, Transport Layer Security (TLS), has risen in accordance with the increasing need for privacy online. Modern cybercampaigns frequently focus on attacking users through the most common web protocols and applications. NSS continues to receive inquiries from enterprise customers during their assessments of vendors that provide SSL/TLS decryption and protection technologies. Figure 15 provides the results of the SSL performance testing for the XG Firewall 750.

Product	NSS-Tested SSL/TLS Throughput (Mbps)
Sophos XG Firewall 750 SFOS v17.0.7 MR7	1,713

Figure 15 - NSS-Tested SSL/TLS Throughput (Mbps)

The XG Firewall 750 is rated by NSS at 1,713 Mbps with SSL/TLS enabled.

NSS-Tested SSL/TLS Throughput is calculated as a weighted average of the traffic that NSS expects an NGFW to experience in an enterprise environment. The validation of functionality was therefore reduced to ciphers tested for performance. For further details on SSL performance, please see the SSL Performance Test Report for this device.

Stability and Reliability

Long-term stability is particularly important for an inline device, where failure can produce a network outage. These tests verify the device's ability to block malicious traffic while under extended load. Products that cannot sustain legitimate traffic while under test will fail.

The device is required to remain operational and stable throughout all these tests, and to block 100% of previously known malicious attacks, raising an alert for each. If any non-allowed traffic passes successfully, caused either by the volume of traffic or by the device failing open for any reason, it will fail the test.

Stability and Reliability	Result
Blocking under Extended Attack	PASS
Passing Legitimate Traffic under Extended Attack	PASS
Behavior of the State Engine under Load	
Attack Detection/Blocking – Normal Load	PASS
State Preservation – Normal Load	PASS
Pass Legitimate Traffic – Normal Load	PASS
Drop Traffic – Maximum Exceeded	PASS
Power Fail	PASS
Backup / Restore	PASS
Persistence of Data	PASS
Stability	PASS

Figure 16 - Stability and Reliability Results

Total Cost of Ownership (TCO)

Implementation of security solutions can be complex, with several factors affecting the overall cost of deployment, maintenance, and upkeep. Each of the following should be considered over the course of the useful life of the solution:

- **Product Purchase** The cost of acquisition.
- **Product Maintenance** The fees paid to the vendor, including software and hardware support, maintenance, and other updates.
- **Installation** The time required to take the device out of the box, configure it, put it into the network, apply updates and patches, and set up desired logging and reporting.
- **Upkeep** The time required to apply periodic updates and patches from vendors, including hardware, software, and other updates.
- **Management** Day-to-day management tasks, including device configuration, policy updates, policy deployment, alert handling, and so on.

For the purposes of this report, capital expenditure (capex) items are included for a single device only (the cost of acquisition and installation).

Installation Hours

Figure 17 depicts the number of hours of labor required to install each device using only local device management options. The table accurately reflects the amount of time that NSS engineers, with the help of vendor engineers, needed to install and configure the device to the point where it operated successfully in the test harness, passed legitimate traffic, and blocked and detected prohibited or malicious traffic. This closely mimics a typical enterprise deployment scenario for a single device.

The installation cost is based on the time that an experienced security engineer would require to perform the installation tasks described above. This approach allows NSS to hold constant the talent cost and measure only the difference in time required for installation. Readers should substitute their own costs to obtain accurate TCO figures.

Product	Installation (Hours)
Sophos XG Firewall 750 SFOS v17.0.7 MR7	8

Figure 17 - Sensor Installation Time (Hours)

Total Cost of Ownership

Calculations are based on vendor-provided pricing information. Where possible, the 24/7 maintenance and support option with 24-hour replacement is utilized, since this is the option typically selected by enterprise customers. Prices are for single device management and maintenance only; costs for central management solutions (CMS) may be extra.

Product	Year 1 Cost	Year 2 Cost	Year 3 Cost	3-Year TCO
Sophos XG Firewall 750 SFOS v17.0.7 MR7	\$21,540	\$5,286	\$5,286	\$32,112

Figure 18 -3-Year TCO (US\$)

• **Year 1 Cost** is calculated by adding installation costs (US\$75 per hour fully loaded labor x installation time) + purchase price + first-year maintenance/support fees.

For the Sophos XG Firewall 750, updates for the first year are included in the initial purchase price and are not counted again in *Year 1 Cost*.

- Year 2 Cost consists only of maintenance/support fees.
- Year 3 Cost consists only of maintenance/support fees.

For additional TCO analysis, including for the CMS, refer to the TCO Comparative Report.
